

PhD Diary Entry for week beginning October 8th 2018

Nathan Hughes

October 19, 2018

Contents

1	General TODOs	2
1.1	TODO Talk to R and J about trying to diagrammatically explain data flow.	2
1.2	TODO Study up on Fick's laws of diffusion	2
1.3	TODO Read Introduction to Diffusion Modelling	2
1.3.1	TODO Revise Partial Diff Equations	2
2	Paper Reviews	2
2.1	TODO Understanding Plant Immunity as a surveillance system to detect invasion [1] . . .	2
2.1.1	Intro	2
2.1.2	Advances in explaining the plant immune system	3
2.1.3	Limitations and incongruities in the MAMP-effector dichotomy	3
2.2	TODO Simple models for complex questions on plant development (Thesis) [2]	4
2.2.1	Chapter 2	4
2.3	DONE Modelling advection nad diffusion of water isotopologues in leaves [3]	5
3	Papers to read	5
3.1	TODO Necrotrophic Pathogens Use the SA Signaling Pathway to Promote Disease Development in Tomato [4]	5
3.2	TODO A single fungal MAP kinase controls plant cell-to-cell invasion by the rice blast fungus [5]	5
3.3	TODO Callose biosynthesis in arabidopsis with a focus on pathogen response: what we have learned within the last decade [6]	5
4	Key words/phrases	5
4.1	PRR	5
4.2	MTI	5
4.3	Effectors	6
4.4	ETS	6
4.5	ETI	6
4.6	MTI-ETI	6
4.7	DAMPs	6
4.8	Kinase	6
4.9	Dichotomy	6
4.10	Advection	6
5	Questions	7

1 General TODOs

1.1 TODO Talk to R and J about trying to diagrammatically explain data flow.

1.2 TODO Study up on Fick's laws of diffusion

Fick's first law

$$J = \frac{dM}{S \bullet dt} \quad J = -D \frac{dC}{dx} \quad \text{Rate of diffusion through unit area}$$

- The negative sign of equation signifies that diffusion occurs in a direction opposite to that of increasing concentration.
- That is, diffusion occurs in the direction of decreasing concentration of diffusant; thus, the flux is always a positive quantity.
- The *diffusion coefficient*, D it does not ordinarily remain constant.
- D is affected by concentration, temperature, pressure, solvent properties, and the chemical nature of the diffusant.
- Therefore, D is referred to more correctly as a *diffusion coefficient* rather than as a constant.

Figure 1: Diffusion

1.3 TODO Read Introduction to Diffusion Modelling

- <http://www.mathematica-journal.com/2012/03/diffusion-modeling/>
 - This could be v.good to try and translate into python as an exercise / practice

1.3.1 TODO Revise Partial Diff Equations

- <https://www.math.uni-leipzig.de/~miersemann/pdebook.pdf>
- <http://tutorial.math.lamar.edu/Classes/DE/TheHeatEquation.aspx>

2 Paper Reviews

2.1 TODO Understanding Plant Immunity as a surveillance system to detect invasion [1]

2.1.1 Intro

- Crop production needs doubled by 2050 by some current estimates
- A lot of work has been done on conceptual models for plant pathogen systems
 - Details in the models vary

- Though they all agree in the observation that plants mainly rely on innate immune systems that are largely controlled by encoded receptors that identify invasion
- It's important to note that models:
 1. Are generalisations and therefore incomplete
 2. Increasing the details of a model decreases its general applicability
 3. Multiple models can be used to explain the same phenomenon
 4. All models should be continually challenged via experimentation to advance scientific knowledge
- Models are full of limitations and narrowly define molecular plant-invader interactions
 - Additionally do not integrate experimental data from diverse systems
- Introduces the *Invasion Model*

2.1.2 Advances in explaining the plant immune system

- Talks about gene-for-gene hypothesis
- And how other research suggests "general elicitors" from microbes which could **not** be used to determine race specificity or were detected by multiple plant species
 - In contrast to pathogen Avr's that induced responses only on particular varieties of a host species
 - These seemingly different observations were regarded as disparate phenomena
 - The identification and characterisation of general elicitors and their receptors in vertebrate immunity helped to further refine the concept in plant immunity
- Charles Janeway postulated the concept of conserved microbial ligands for innate immunity to account for lapses in the conceptual model of vertebrate immunity
 - He reasoned that microbes possess pathogen-associated molecular patterns (PAMPs)
 - That are recognised by host pattern recognition receptors (PRRs) as nonself
 - He anticipated that PRRs perceive microbe-derived conserved general structural patterns that are critical for the organism and require significant changes to avoid recognition
- PAMP is noted to be a misnomer, as it often concerns molecules present in both pathogenic and nonpathogenic organisms
 - Hence why we now use the term MAMPs (microbe-associated molecular pattern)
- Talks about zigzag model (see figure in key words/phrases)

2.1.3 Limitations and incongruities in the MAMP-effector dichotomy

- Continued research into plant microbe-interactions have identified a number of concerns over the MTI-ETI dichotomy

- Issues are raised with the conceptual layout of the model in distinct phases governed by discrete responses
- A primary concern is the relationships between:
 - MAMPs and Effectors
 - PRRs and R proteins
 - MTI and ETI
- These relations also ignore DAMPs
- The zigzag model does not acknowledge the number, kinetics and combined action of multiple receptor ligands that govern these interactions
- Additionally, pathogen perception and response are illustrated over an ambiguous spatial and temporal frame, obscuring the model's intention to represent evolution or a particular cellular encounter
- The zigzag model also doesn't account for previous life history events of the host or invader prior to the interaction, which may influence the outcome of said interaction

2.2 **TODO** Simple models for complex questions on plant development (Thesis) [2]

2.2.1 Chapter 2

- To form different tissues, cells need to differentiate
- Plant cells mostly can't move
- Requirements for coordination of developmental and functional needs
- To do this cells use a number of signalling molecules
- Animals use different systems for communication of inter-cellular information
 - A Delta-notch system is one example
- Protein-Protein interactions are obviously impossible between plants, unlike in animals
- Plants can achieve results using a "non-cell-autonomous proteins" method
 - i.e. Protein signals that are transcribed in one cell and affect transcription in another
 - Like a factory which outsources some of its labour?
- These proteins move symplastically through PD channels
- Symplastic transport comes in two forms:
 1. Generic: the passive movement of all sufficiently small molecules; this is non-targeted and is diffusion driven
 2. Targeted: targeted symplastic transport is a container term for a variety of different mechanisms that allow symplastic movement of molecules that depend on it
- Virus' create their own "movement proteins" to facilitate the crossing via targeted symplastic movement

- This process maybe involve structural alterations of the plasmodesmata, which affect the non-targeted transport properties
- Molecules moving by non-targeted symplastic transport may include plant hormones, small RNAs and small proteins
 - Providing they are small enough
 - This means that they fit the "size exclusion limit" (SEL)
 - The SEL is developmentally regulated and varies among different tissues
- The aperture of plasmodesmata is controlled through the deposition and degradation of callose
 - by callose synthase (Ca1S aka GSL gene family) and β -1,3-glucanase respectively
 - Further regulation takes place by other factors too [7]

2.3 **DONE** Modelling advection nad diffusion of water isotopologues in leaves [3]

- Not relevant

3 Papers to read

- 3.1 **TODO** Necrotrophic Pathogens Use the SA Signaling Pathway to Promote Disease Development in Tomato [4]
- 3.2 **TODO** A single fungal MAP kinase controls plant cell-to-cell invasion by the rice blast fungus [5]
- 3.3 **TODO** Callose biosynthesis in arabidopsis with a focus on pathogen response: what we have learned within the last decade [6]

4 Key words/phrases

4.1 PRR

- [Host] Pattern recognition receptors
- Used to recognise PAMPs as "nonself" materials

4.2 MTI

- MAMP-triggered immunity
- Because of the redundancy of PAMPs as an idea, this is preferred

4.3 Effectors

- Are proteins expressed by plant pathogens
- They aid infection of specific plant species
- Are central to understanding complicated interplay between plants and their pathogens

4.4 ETS

- Effector-Triggered Susceptibility

4.5 ETI

- Effector-Triggered Immunity

4.6 MTI-ETI

- A juxtaposed relationship between MTI-ETI is often misunderstood
- For example, some would believe that the processes are independent and therefore not at a similar level

4.7 DAMPs

- Damage associated molecular patterns

4.8 Kinase

- Is an enzyme that catalyses the transfer of phosphate groups from high-energy, phosphate donating molecules to specific substrates

4.9 Dichotomy

- A division or contrast between two things that are or are represented as being opposed or entirely different
- e.g. 'a rigid dichotomy between science and the DUP'

4.10 Advection

- The transfer of heat or matter by the flow of a fluid

5 Questions

- Regarding DAMPs and general damage control there must be some overlap or at least connection in the pathways that ultimately lead to repair or maintenance
- Are plants/cells aware of other cells around them. i.e. if there was a "perfect" invasion and a pathogen prevented the cell sending any signals and it just "stopped" communicating, would the border cells know something was up and try to correct?
 - Similarly, if you perfectly removed a group of cells, a plant repairs itself what's this communication method?
- Bacteria have been attacking plants for millions of years, why haven't they won, yet we fight them with anti-biotics for a century and they're looking like they'll overcome pretty quickly
- Two identical plants, control conditions, infected with same pathogen, is it likely for them to develop a similar response or is there a level of ambiguity in the choices made to protection, prevention and developing immunity?
- If a crab eats a plant, does the plant think its a fungal attack?
- Do many attackers perform prolonged, dormancy based attacks or is it an all out attack most of the time?
- During an attack, is it possible to something like bacteria to adapt during the attack and to adapt, or is that too small a timescale?
 - If so is this a potential concern for any kind of analysis, that is to say should we expect "experimental tactics" from the invaders?
- Things that the plant makes, are they somehow signed by the cell to prove authenticity or how do receptors / w/e know that it isn't foreign
- Is the MAMPs response like a magnet i.e. how mechanical is the process, like molecules naturally drawn together v.s. a more fluid process of decision making and evaluation of the attack
- Mutants with bad callose deposition reportedly don't make it much further than embryo stage, what other functions than PD does it affect?
